

Let's apply the relationship of heat, entropy, and temperature to a contemporary challenge!

We'd like to maximize the efficiency of any process that is based on heat flow as an input.

Coal

Nuclear

Combustion engine

Solar concentrating plant

Figure 1: Just a few examples of heat engines.

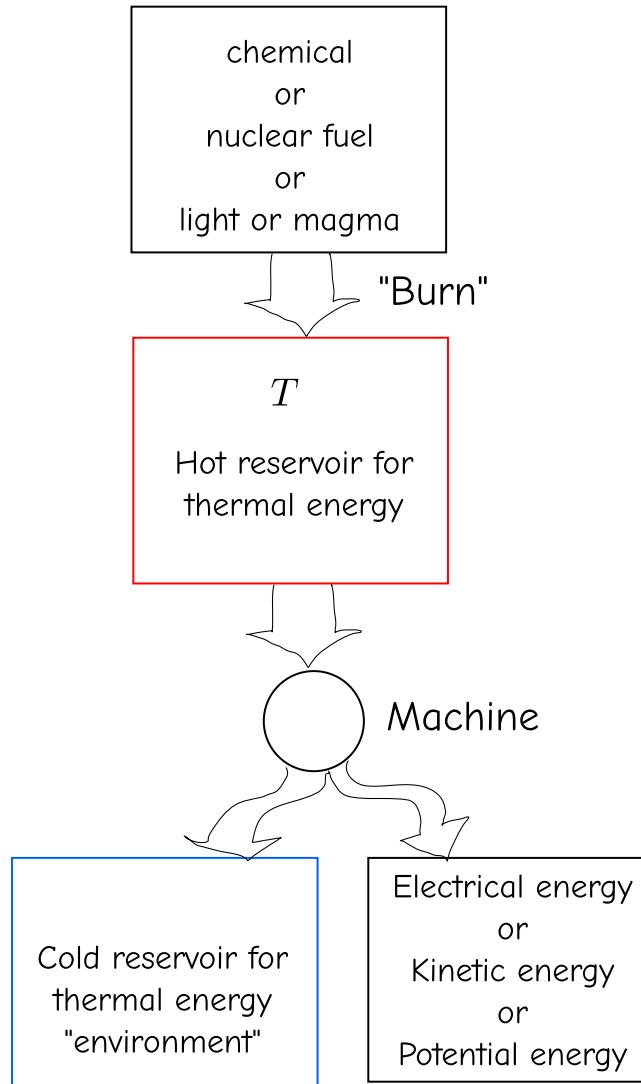

Figure 2: Energy flow diagram

**Energy flow diagram** The efficiency of the machine is

$$\text{efficiency} = \frac{W}{Q_{\text{in}}} \quad (1)$$

$$\text{e.g.} = \frac{500 \text{ J}}{1000 \text{ J}} = 50\% \quad (2)$$

For a car engine,  $T_H \approx 600 \text{ K}$  and  $T_C \approx 300 \text{ K}$ .

Remember that  $\Delta S = \frac{Q}{T}$ , and  $\Delta S_{\text{tot}} \geq 0$ .
